

Chapter 7

Signals

Signal Lifecycle, Long Version

1. A signal is **generated** and directed to a process
2. If the process **ignores** this signal, the signal is discarded
 - KILL, STOP cannot be ignored
3. If the process **blocks** this signal, it is kept **pending** until the process unblocks it
 - KILL, STOP cannot be blocked
4. Otherwise, the signal is **delivered** to the process
5. Once delivered, the signal must be **handled**
 - The **default** action is to *terminate* the process;
 - the process is *stopped* by STOP (^Z), TTIN, TTOU, TSTP (^S — type ^Q to continue)
 - CONT *continues* the process; CHLD is ignored
 - The default action is not taken if a signal handler has been installed for **catching** the signal
 - KILL, STOP cannot be caught

Asynchronous Events: UNIX Signals

Signal lifecycle, short version:

1. A signal is **generated** by the occurrence of a particular event
2. A generated signal is **delivered** to a process
3. Once delivered, the signal must be **handled**

Two kinds of signals:

- **Synchronous events:** produced by the target process
SIGSEGV (11), SIGPIPE, SIGFPE, SIGILL, SIGABRT are typically synchronous, but can also be sent from another process
- **Asynchronous events:** produced by another process
SIGKILL (9), SIGTERM, SIGINT, SIGQUIT, SIGHUP (1), SIGCHLD, SIGSTOP, SIGUSR1, SIGUSR2

Sending Signals

- **kill(1)** or shell builtin:

```
kill [ -s signal ] pid ...
kill -l [ signal ]
```

```
kill -s sigspec [pid | jobspec]
kill -n signum [pid | jobspec]
kill [ -sigsig ] [pid | jobspec]
```
- **killall(1)** — by command name
- **kill(2):**

```
#include <sys/types.h>
#include <signal.h>
int kill(pid_t pid, int sig);
```
- **raise(3):** sends a signal to calling process
- **abort(3):** sends *SIGABRT* to calling process
- **alarm(3):** sends *SIGALRM* to caller after specified time

Interface to Signal Handling

- **sigprocmask(2)**: blocking and unblocking signals
- **sigpending(2)** allows the examination of pending signals
- **sigsuspend(2)**: temporarily replaces the signal mask and then suspends the process until a signal is received.
- **sigaction(2)** allows to install handlers — *SIG_IGN* is the special handler used for ignoring; *SIG_DFL* refers to the default action

USP Program 8.4 — password.c

```
int password(const char *prompt, char *passbuf, int passmax) {
    int fd, firsterrno = 0;
    sigset_t signew, sigold;
    char termbuf[L_ctermid];
    if (ctermid(termbuf) == NULL) { /* find the terminal name */
        errno = ENODEV;
        return -1;
    }
    if ((fd = open(termbuf, O_RDONLY)) == -1) /* open terminal */
        return -1;
    if ((sigemptyset(&signew) == -1) | /* blocked signals */
        (sigaddset(&signew, SIGINT) == -1) ||
        (sigaddset(&signew, SIGQUIT) == -1) ||
        (sigaddset(&signew, SIGTSTP) == -1) ||
        (sigprocmask(SIG_BLOCK, &signew, &sigold) == -1) ||
        (setecho(fd, 0) == -1)) { /* set terminal echo off */
        firsterrno = errno;
    }
    sigprocmask(SIG_SETMASK, &sigold, NULL);
    r_close(fd);
    errno = firsterrno;
    return -1;
}
if ((r_write(STDOUT_FILENO, (char*)prompt, strlen(prompt))
    == -1) ||
    (readline(fd, passbuf, passmax) == -1)) /* read password */
firsterrno = errno;
else
    passbuf[strlen(passbuf) - 1] = 0; /* remove newline */
if ((setecho(fd, 1) == -1) && !firsterrno) /* turn echo back on */
    firsterrno = errno;
if ((sigprocmask(SIG_SETMASK, &sigold, NULL) == -1)
    && !firsterrno)
    firsterrno = errno;
if ((r_close(fd) == -1) && !firsterrno) /* close terminal */
    firsterrno = errno;
return firsterrno ? errno : firsterrno, -1: 0;
```

USP Program 8.1 — blocktest.c

```
int main(int argc, char *argv[]) {
    double y = 0.0; int i, repeatfactor = atoi(argv[1]);
    sigset_t intmask;
    if (sigemptyset(&intmask) || sigaddset(&intmask, SIGINT))
        perror("Failed to initialize the signal mask"); return 1;
    for (;;) {
        if (sigprocmask(SIG_BLOCK, &intmask, NULL) == -1) break;
        fprintf(stderr, "SIGINT signal blocked\n");
        for (i = 0; i < repeatfactor; i++) y += sin((double)i);
        fprintf(stderr, "Blocked calculation is finished, y = %f\n", y);
        if (sigprocmask(SIG_UNBLOCK, &intmask, NULL) == -1)
            break;
        fprintf(stderr, "SIGINT signal unblocked\n");
        for (i = 0; i < repeatfactor; i++) y += sin((double)i);
        fprintf(stderr, "Unblocked calculation finished, y=%f\n", y);
    }
    perror("Failed to change signal mask"); return 1;
}
```

sigaction(2)

```
int sigaction(int signum, const struct sigaction *act,
             struct sigaction *oldact);
```

- *signum* cannot be *SIGKILL* or *SIGSTOP*.
- If *act* is non-null, it defines the new action for signal *signum*.
- *SIG_IGN* is the special handler used for ignoring.
- *SIG_DFL* refers to the default action.
- If *oldact* is non-null, the previous action is saved in *oldact*.

struct *sigaction*

```
struct sigaction {           /* preliminary */
    void (*sa_handler)(int);
    sigset_t sa_mask;
    int sa_flags;
}
```

- *sa_mask* contains signals blocked during execution of the signal handler in addition to *signum*.
- *sa_flags* may contain the following:

POSIX: *SA_NOCLDSTOP*

Linux (additionally): *SA_ONESHOT*, *SA_ONSTACK*,
SA_RESTART, *SA_NOMASK*, *SA_SIGINFO*

USP Example 8.15

```
#include <signal.h>
#include <stdio.h>
struct sigaction act;
/* Find current signal handler */
if (sigaction(SIGINT, NULL, &act) == -1)
    perror("Failed to get old handler for SIGINT");
else if (act.sa_handler == SIG_DFL)
{ /* ignore SIGINT */
    act.sa_handler = SIG_IGN; /* set handler to ignore */
    if (sigaction(SIGINT, &act, NULL) == -1)
        perror("Failed to ignore SIGINT");
}
```

USP Example 8.16

```
void catch_ctrl_c(int signo)
{ char handmsg[] = "I found Ctrl-C\n";
    int msglen = sizeof(handmsg) - 1;
    write(STDERR_FILENO, handmsg, msglen); }

...
struct sigaction act;
...
act.sa_handler = catch_ctrl_c;
sigemptyset(&act.sa_mask);
act.sa_flags = 0;
if (sigaction(SIGINT, &act, NULL) < 0)
    /* handle error here */
...
• fprintf() and strlen() are not async-signal safe!
```

Frequent Uses of Signal Handlers

- Graceful termination
 - set termination flag (Program 8.5)
 - release resources — typically calling `exit`
- Trigger status messages (Program 8.6)
- Trigger configuration reload (many daemons)

The Problem with `pause()` — USP Exercise 8.21

```
static volatile sig_atomic_t sigreceived = 0;

while(sigreceived == 0)
    pause();

• Assume the handler sets sigreceived to 1
• What happens if a signal is delivered between the test of
sigreceived and the call of pause?
• Blocking the signal for testing sigreceived ...
• Unblocking and suspending needs to be atomic!
    => sigsuspend()
```

Waiting for Signals

- `int pause(void);`
susends until a signal is delivered that either has a handler or terminates the process.
- `int sigsuspend(const sigset_t *mask);`
temporarily replaces signal mask and then suspends until a signal is received
- `int sigwait(const sigset_t *set, int *sig);`
susends until signal from `set` is pending; then unblocks and removes that signal from pending set.

PUP Example 5.20

```
#include <signal.h>
volatile int signal_received = 0; /* external static variable */
...
sigset_t sigset, sigoldmask;
int signum;

sigprocmask(SIG_SETMASK, NULL, &sigoldmask);
sigprocmask(SIG_SETMASK, NULL, &sigset);
sigaddset(&sigset, signum);
sigprocmask(SIG_BLOCK, &sigset, NULL);
sigdelset(&sigset, signum);
while(signal_received == 0)
    sigsuspend(&sigset);
sigprocmask(SIG_SETMASK, &sigoldmask, NULL);
```

Concurrency Introduced by Signals

- While executing library function (or system call) *f()*, a program may catch a signal
- If the signal handler executes *f()*, too, two incarnations of *f()* exist concurrently
- ⇒ *f()* has to be **reentrant!**
 - Use only **async-signal safe** calls in signal handlers!
 - Carefully analyze shared data structures for possible interference.
- Block signals for avoiding interference.
- Check return behaviour of system calls in program for signals (*EINTR*) — in doubt, restart system call.

break and continue in Nested Loops — Problem

```
for ( ... )
{
    ...
    for ( ... )
    {
        ...
        if ( disaster() )
            break; /* breaks only out of inner loop! */
        ...
    }
    ...
}
... /* clean up the mess */
```

Some languages allow to break out of specified loops.

break and continue in Nested Loops — Another Solution

```
for ( ... )
{
    ...
    for ( ... )
    {
        ...
        if ( disaster() )
            goto error; /* breaks out of both loops! */
        ...
    }
    ...
}
error: ... /* clean up the mess */
```

Labels are **local** to the function.

longjmp and *setjmp* — non-local goto

- int *setjmp(jmp_buf env)* saves the stack context/environment in *env* for later use by *longjmp()* and returns 0. The stack context will be invalidated if the function which called *setjmp()* returns.
- void *longjmp(jmp_buf env, int val)* restores the environment saved by the last call of *setjmp()* with the corresponding *env* argument. After *longjmp()* is completed, program execution continues as if the corresponding call of *setjmp()* had just returned the value *val* (never 0).
- **goto considered harmful ...**

siglongjmp and *sigsetjmp*

- Analogous to *longjmp* and *setjmp*, but also can save signal mask in environment.
- *goto* still considered harmful ...

siglongjmp and *sigsetjmp* Example: USP Program 8.12

```
static sigjmp_buf jmpbuf;
static volatile sig_atomic_t jumpok = 0;
void int_handler(int errno)
{ if (jumpok == 0) return; else siglongjmp(jmpbuf, 1); }

void main(void)
{ struct sigaction act;
  act.sa_handler = int_handler; act.sa_flags = 0;
  sigemptyset(&act.sa_mask);
  if (sigaction(SIGINT, &act, NULL) == -1)
  { perror("Error setting up SIGINT handler"); return 1; }
  ...
  if (sigsetjmp(jmpbuf, 1))
    fprintf(stderr, "Returned to main loop due to ^C\n");
  jumpok = 1;
  while (1) ... /* start of main loop */
```
